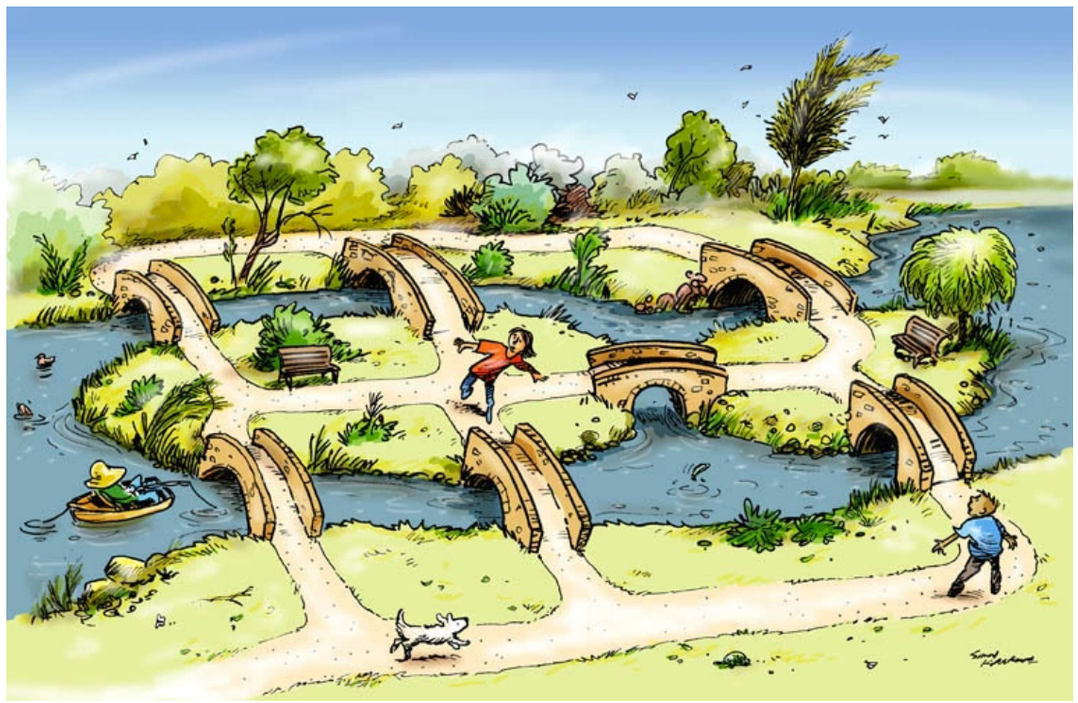
Historical Perspective

With the Seven Bridges of Königsberg problem, Euler in 1737 laid the foundations of the graph theory.

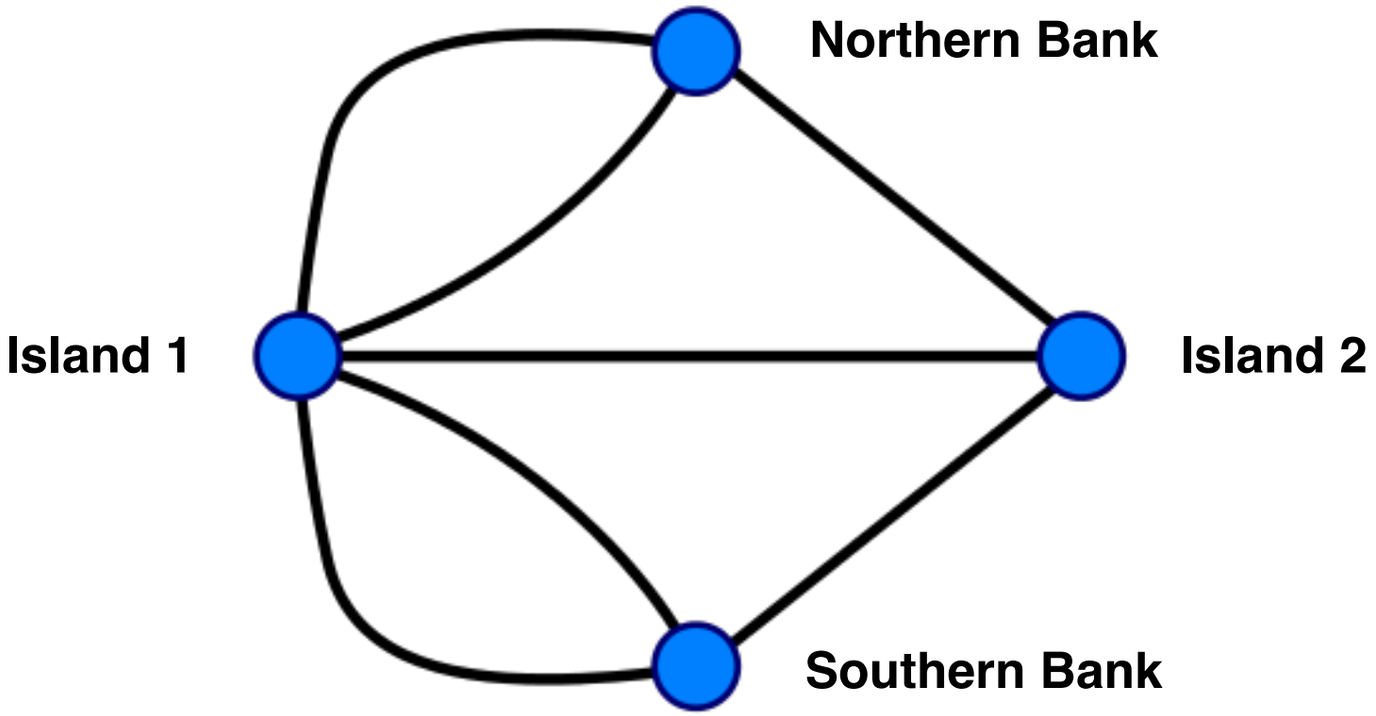


Simon Kneebone – simonkneebone.com

- Find path (Eulerian Path) that traverses all the Pregel's bridges.
- Find walk (Eulerian Circuit) that traverses all the Pregel's bridges and has the same starting and ending point.

Solution

Describe the problem as a graph where the nodes represent the 4 locations and the edges correspond to the bridges



Eulerian path exists only if zero or 2 nodes are connected by an odd number of bridges.

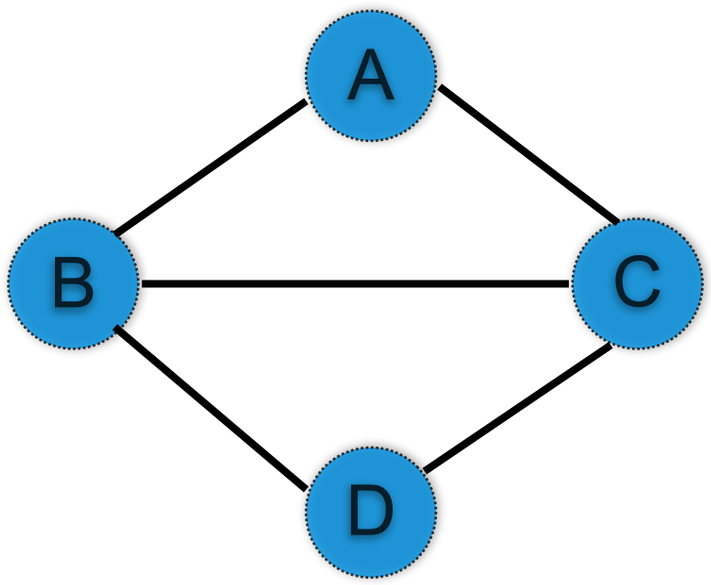
Eulerian circuit exists only if zero nodes are connected by an odd number of bridges.

Graph Definition

A graph is a pair G=(V,E) consisting of two sets:

- V is a set of elements called Nodes or Vertices.
- E is a set of pairs (v_i,v_j) where $v_i \in V$ and $v_j \in V$.

The pairs E are links between two nodes and are called Edges

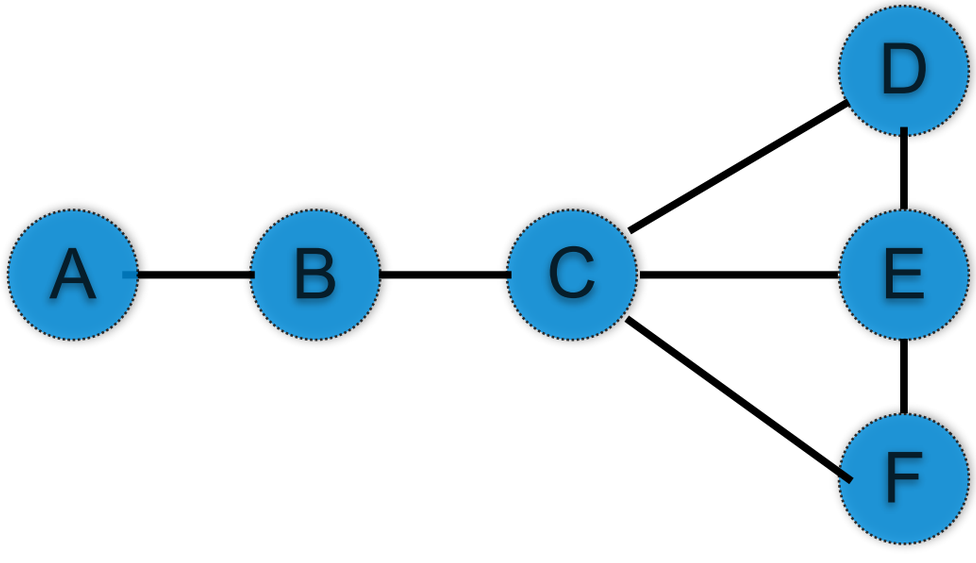


V = {A; B; C; D}

E = {(A,B); (A,C); (B,C); (B,D); (C,D)}

Undirected Graph

Undirected graph is a network where the relationship between nodes are symmetric.

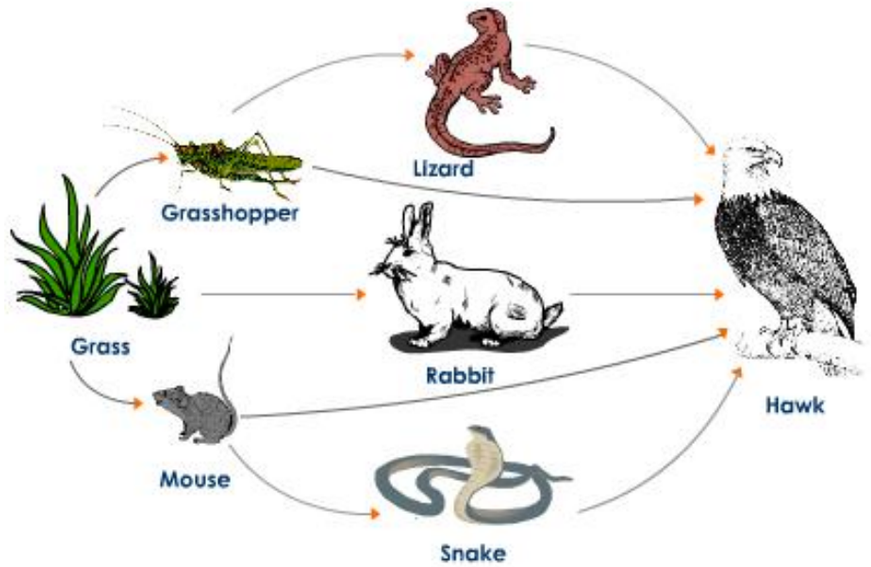


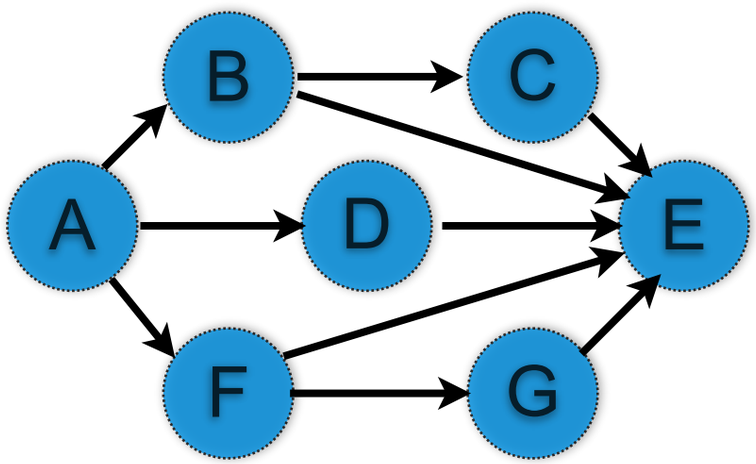
V = {Group of People}

E = {Pairs of Friends}

Directed Graph

Directed graph is a network where the relationship between nodes are asymmetric. In this case the edges are directed lines.



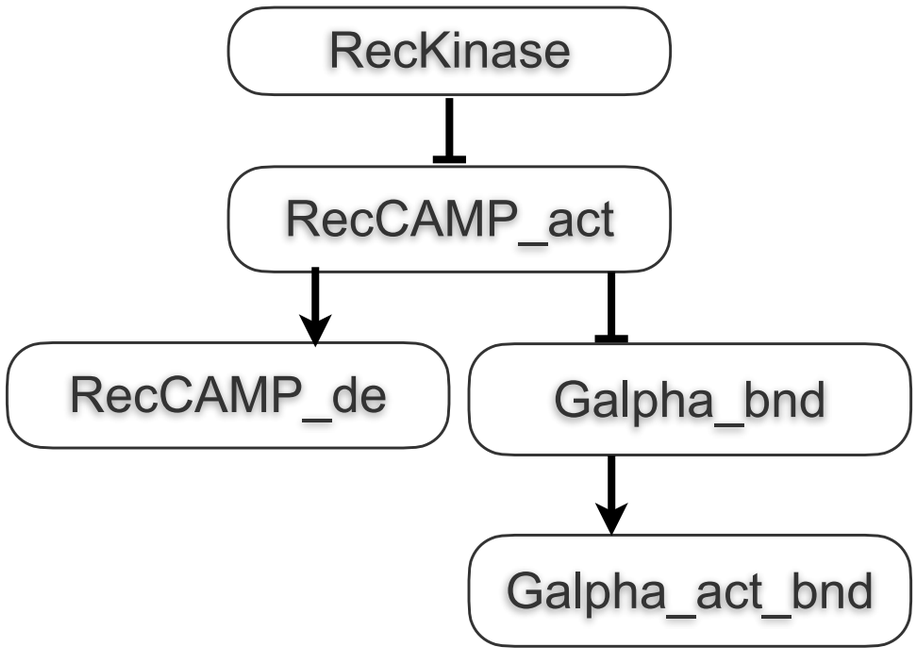


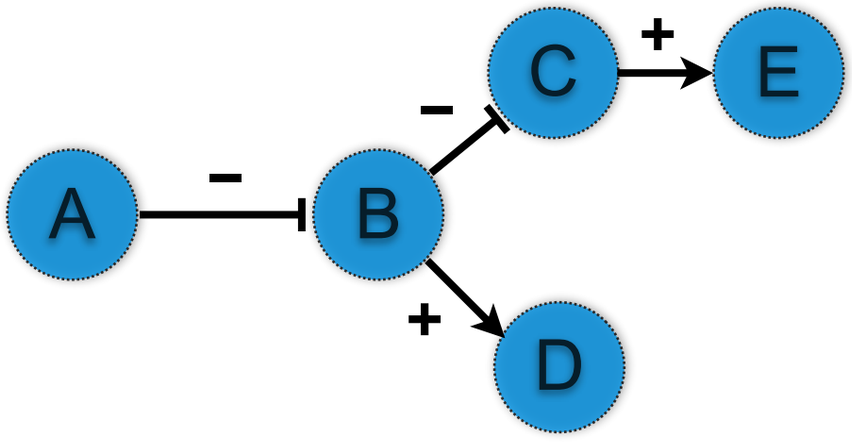
V = {Group of Animals}

E = {Pray/Predator Relationships}

Signed Directed Graph

Signed Directed graph is a network where the relationship between nodes are asymmetric and have positive or negative associated signs





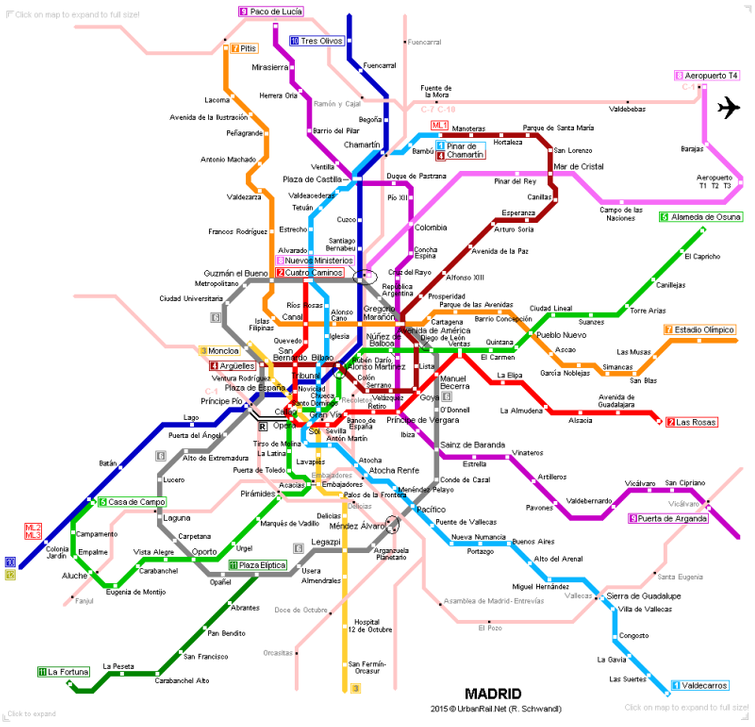
V = {Group of Genes}

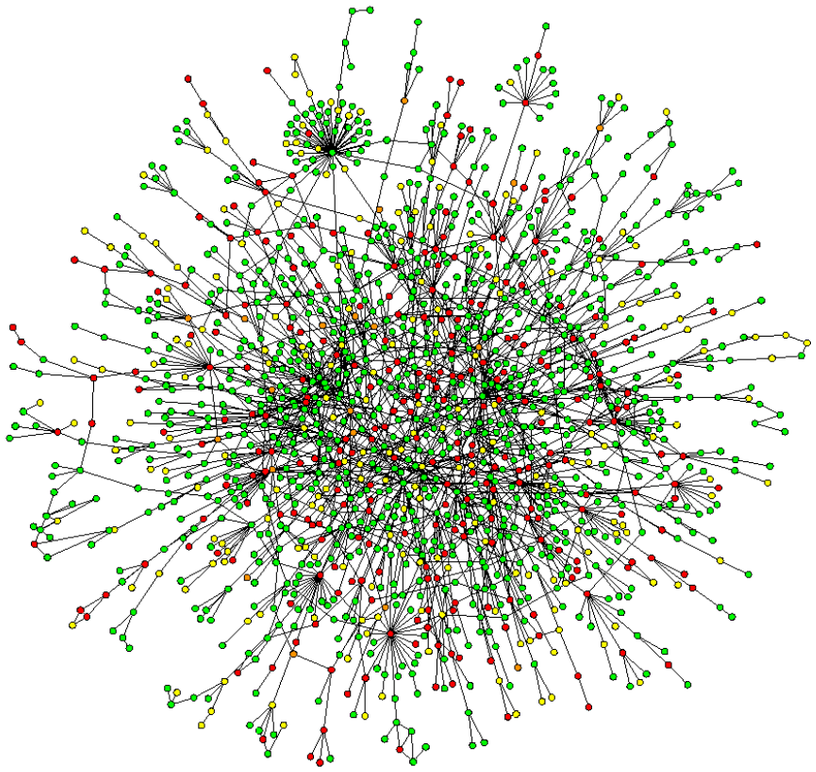
E = {Activation/Inhibition Relationships}

Graph and Networks

Graphs can be used to represent any observed network.

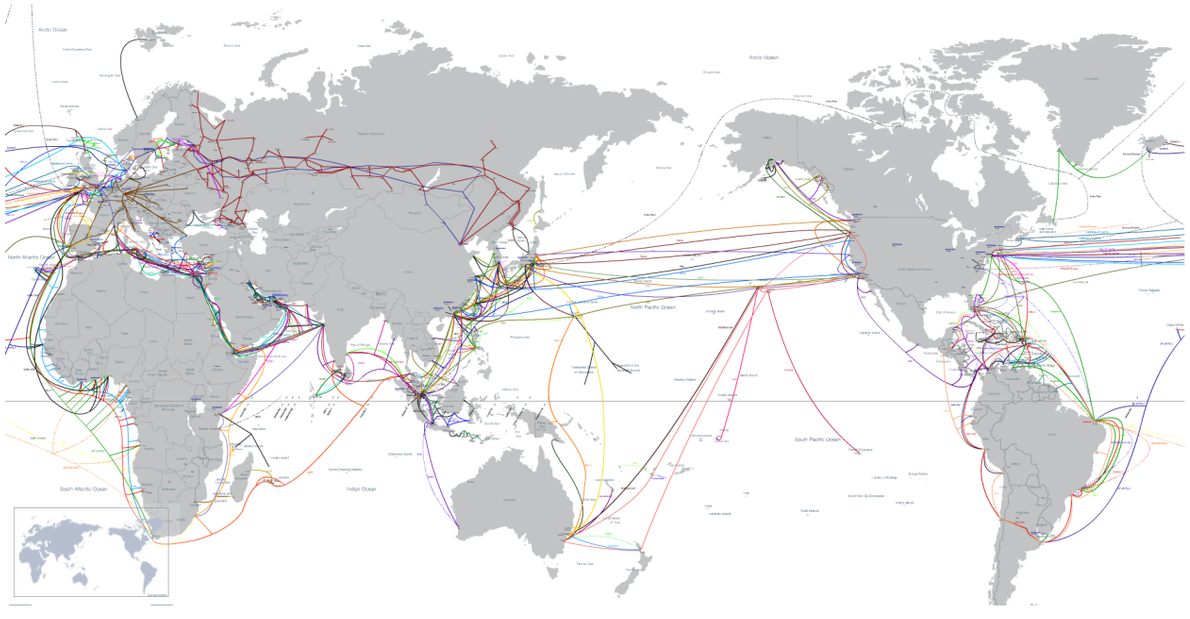
Networks in nature tend to be highly complex





Madrid Metro

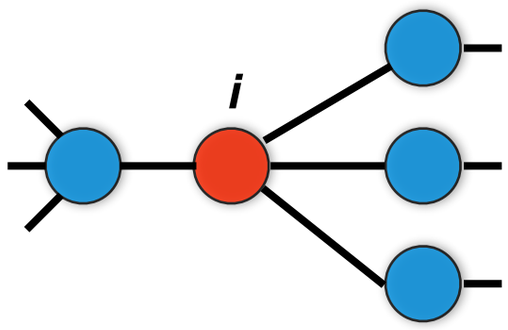
Internet connections



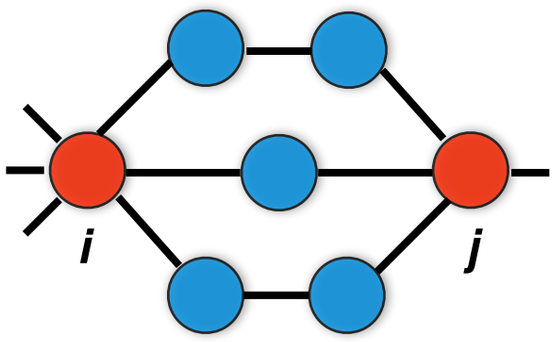
Yeast interactome

Network properties (I)

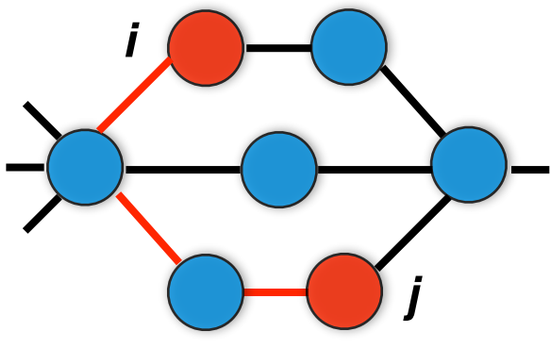
The topology of the network defines its properties. The level of connectivity among the nodes depends on the number of edges.



Degree k_i = number of links connected to node i



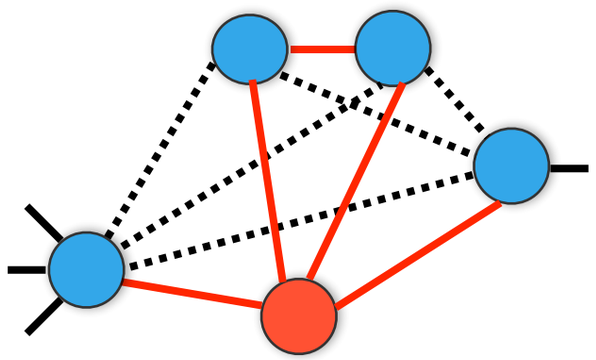
Distance d_{ij} = shortest path between nodes i and j



Diameter D = longest path between all pairs of nodes

Network properties (II)

The topology of the network defines its properties. The level of connectivity among the nodes depends on the number of edges.

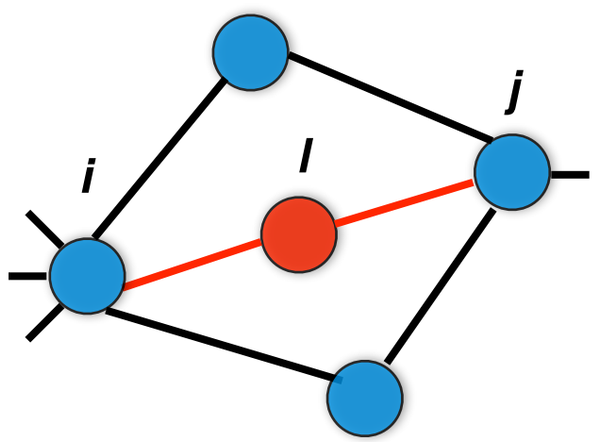


Transitivity or Clustering Coefficient

$$c_i = \frac{2e_i}{k_i(k_i - 1)}$$

k_i = number of nodes connected to *i*

e_i = number of edges between the k_i nodes



Betweenness

$$g_l = \sum_{i \neq l \neq j} \frac{\sigma_{ij}(l)}{\sigma_{ij}}$$

σ_{ij} = number of shortest path between *i and j*

σ_{ij}(l) = number of shortest path passing through node *l*

Types of Network

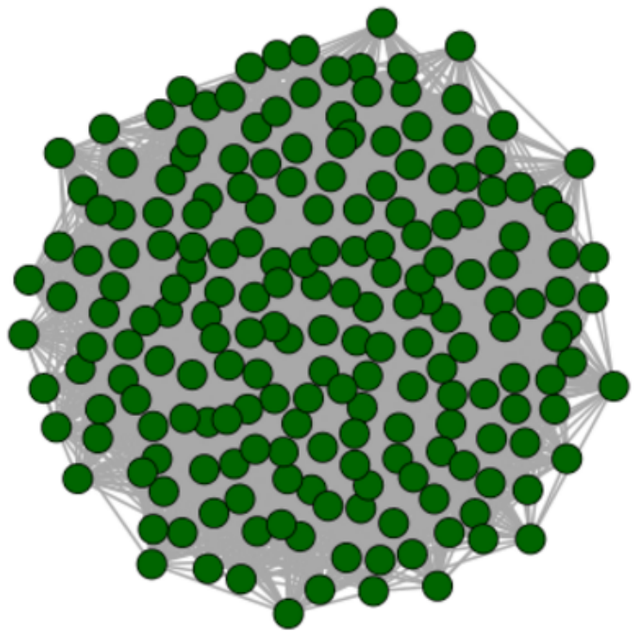
The topology of the network depends on the distribution of the degree for all the nodes.

We can define three types of network:

- Random network: generated by a constant probability of having an edge between two nodes.
- Small-world network: when the degrees follow a Poisson distribution
- Scale-Free network: the degrees follow a Power Law distribution

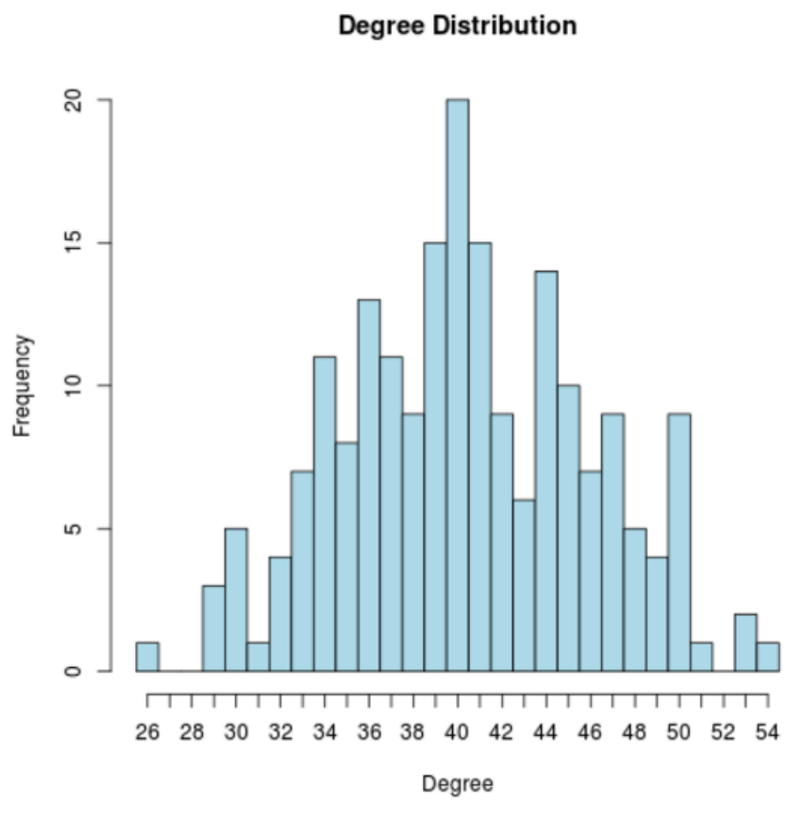
Random Network

Can be generated by Erdős–Rényi model which assume a constant probability of generating edges between nodes.



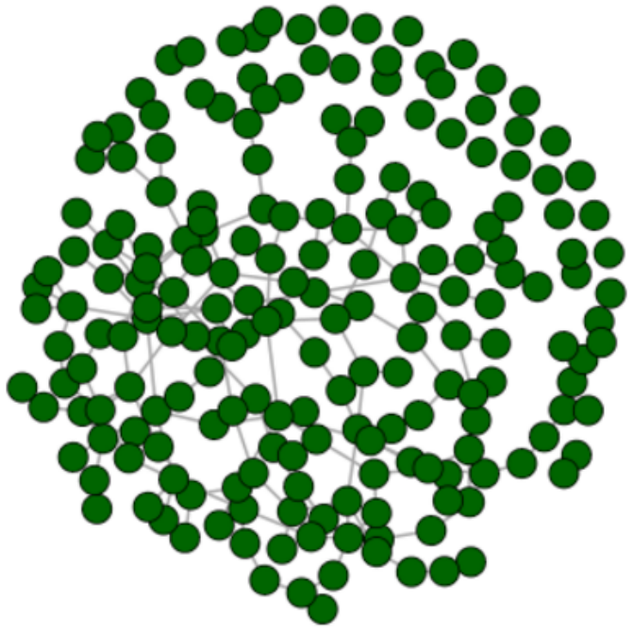
- High node degree ⇒ low average path length
- Degree distribution tends to be a Gaussian
- High Transitivity
- Small Betweenness

Degree = 40.3
Transitivity = 0.2
Betweenness = 79.3



Small-World Network

Generated by a Watts–Strogatz model.

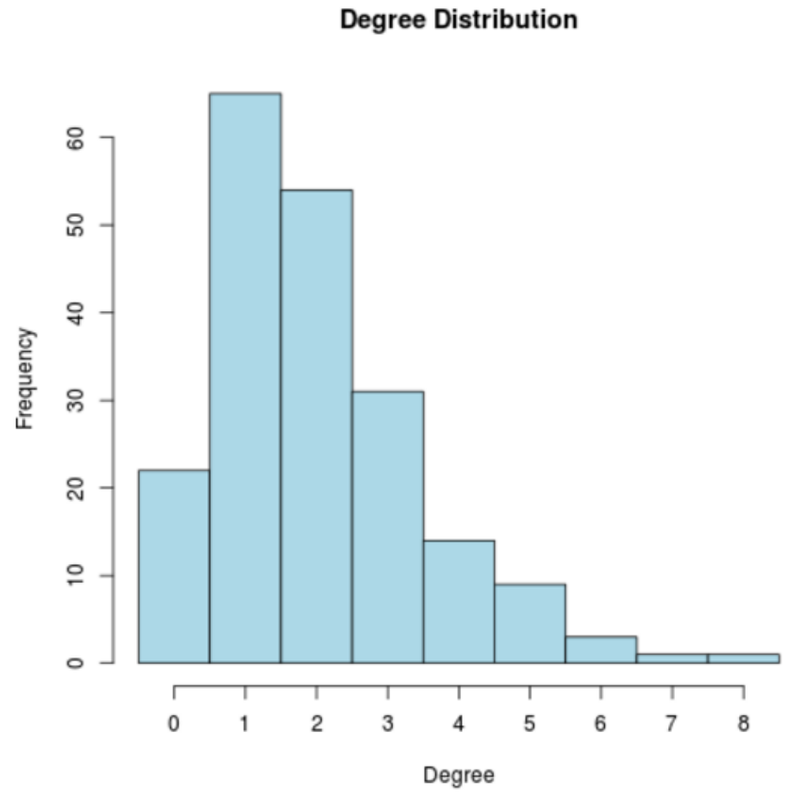


- Low node degree ⇒ “Six degrees of separation”
- Degree follow a Poisson distribution
- Low Transitivity than random
- Higher betweenness than random

$$p(k) = \frac{\lambda^k e^{-\lambda}}{k!}$$

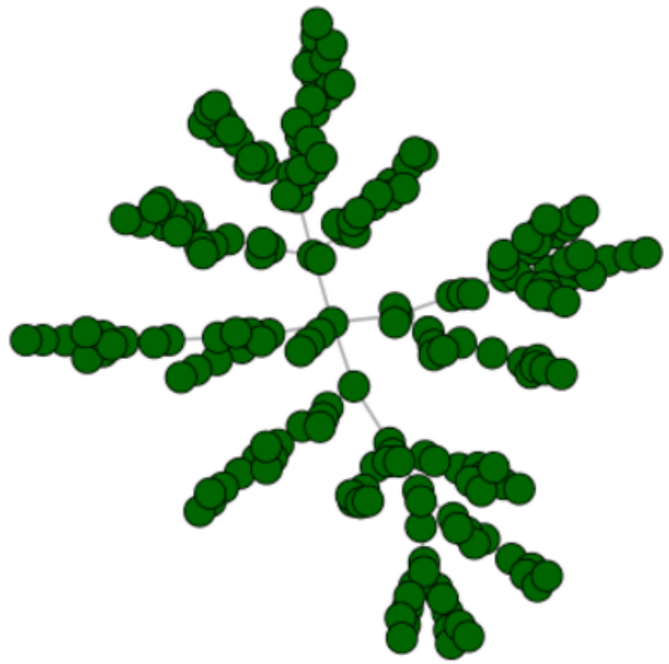
λ = the average value of the distribution
k = number of observed events

Degree = 2
Transitivity = 0.01
Betweenness = 394.9



Scale-Free Network

Generated by the Barabasi-Albert model.

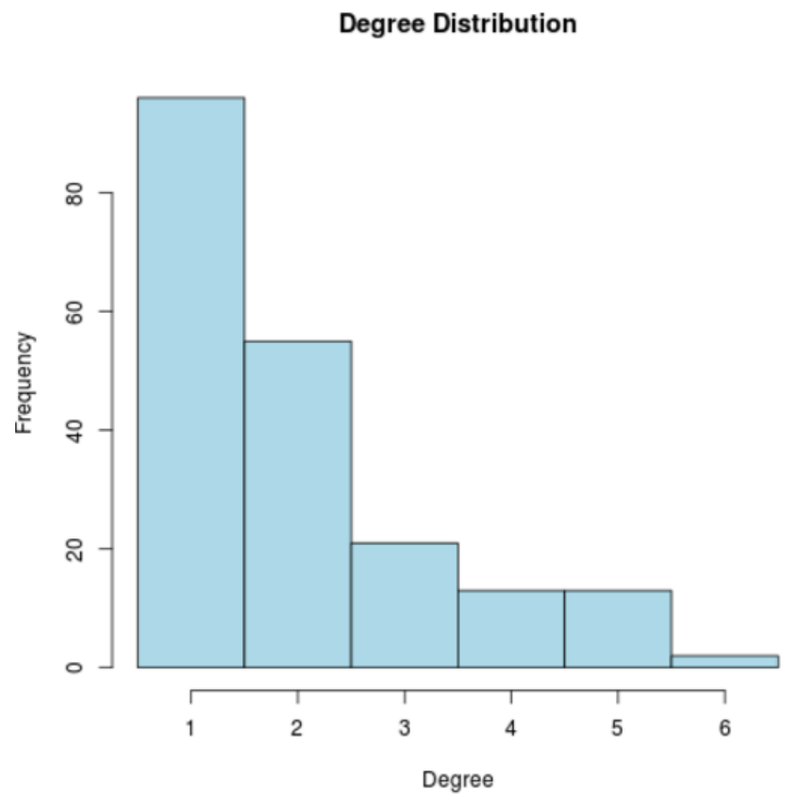


- Smallest degree
- Degree follow a Power Law distribution
- Lowest Transitivity
- Highest Betweenness

$$p(k) = Ax^{-k}$$

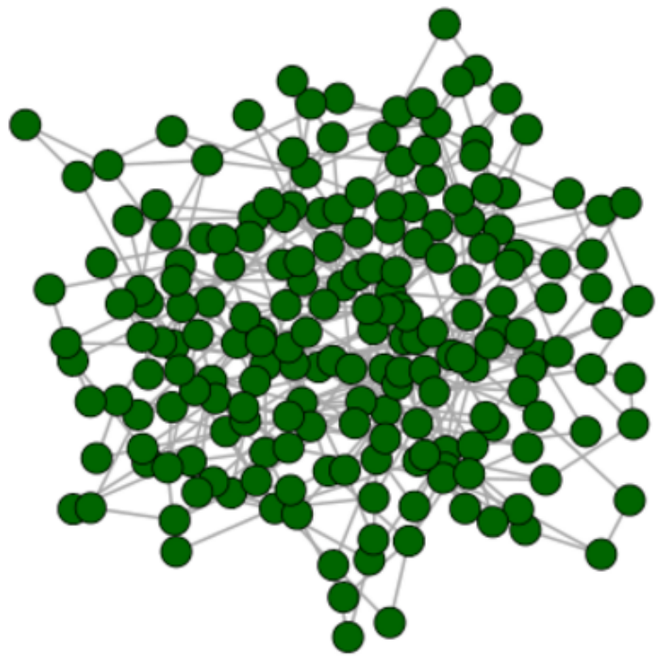
x = is a constant
k = number of observed events

Degree = 2
Transitivity = 0
Betweenness = 753.4



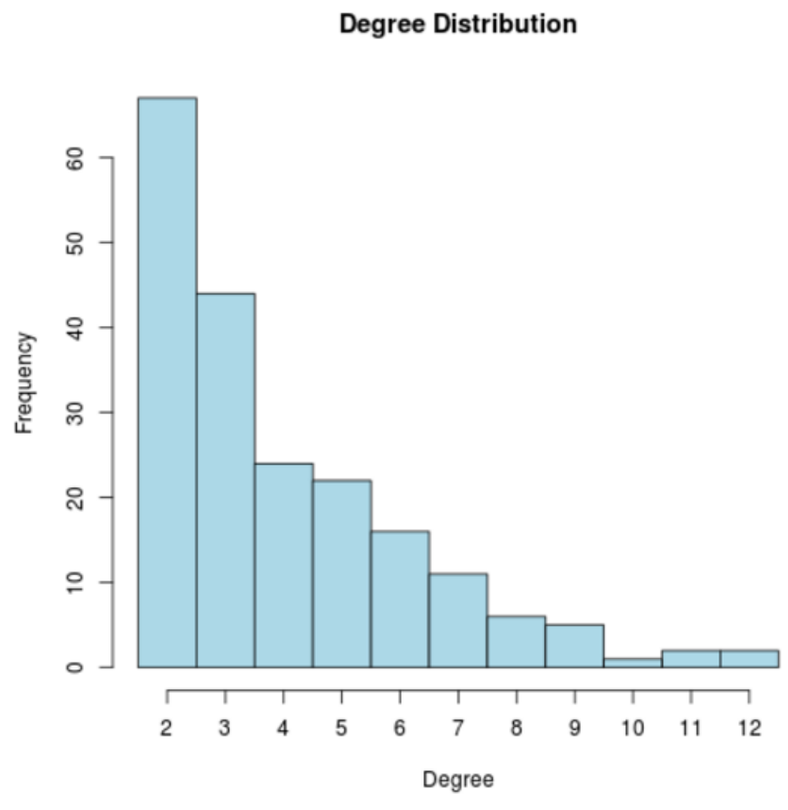
Biological Network

Similar to Small-World and Scale-Free networks



- Small degree
- Average path length proportional to *ln(ln(#nodes))*
- Transitivity high than Small-World and Scale Free
- Betweenness lower than Small-World and Scale Free

Degree = 4.0
Transitivity = 0.04
Betweenness = 290.4

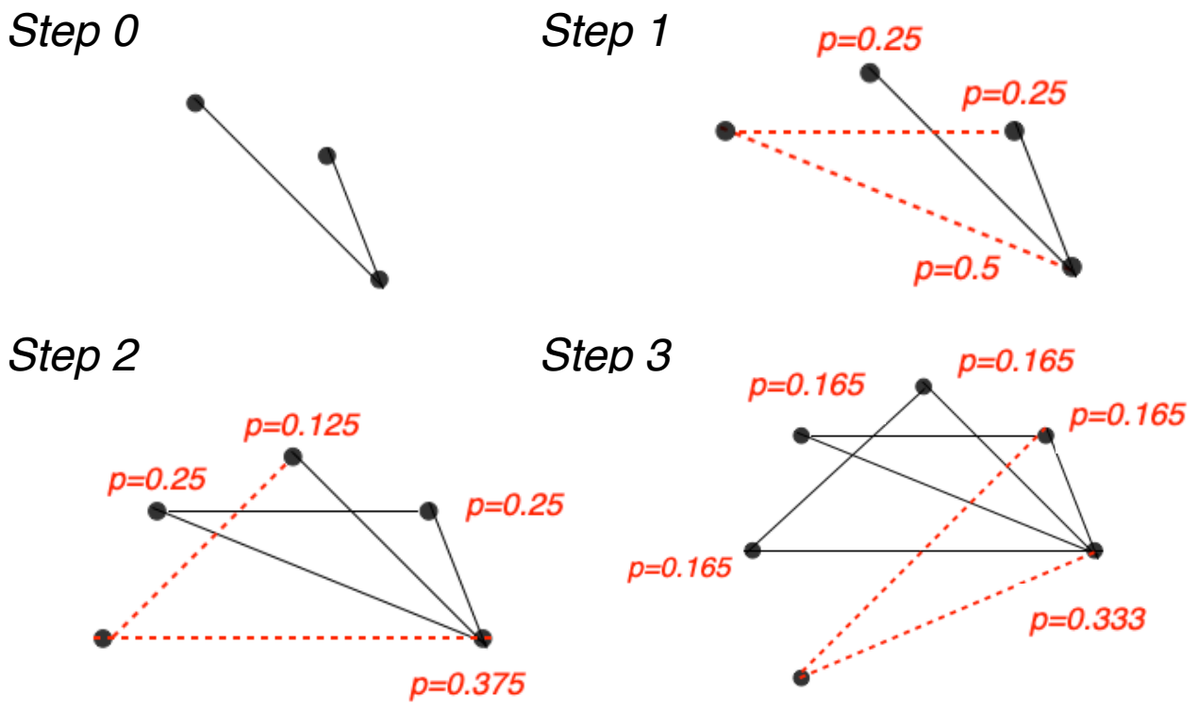


Random Graph Generation

- Random Graph: Given a graph with *N* nodes and all the possible Nx(N-1)/2 undirected edges select each of them with an independent probability *P*

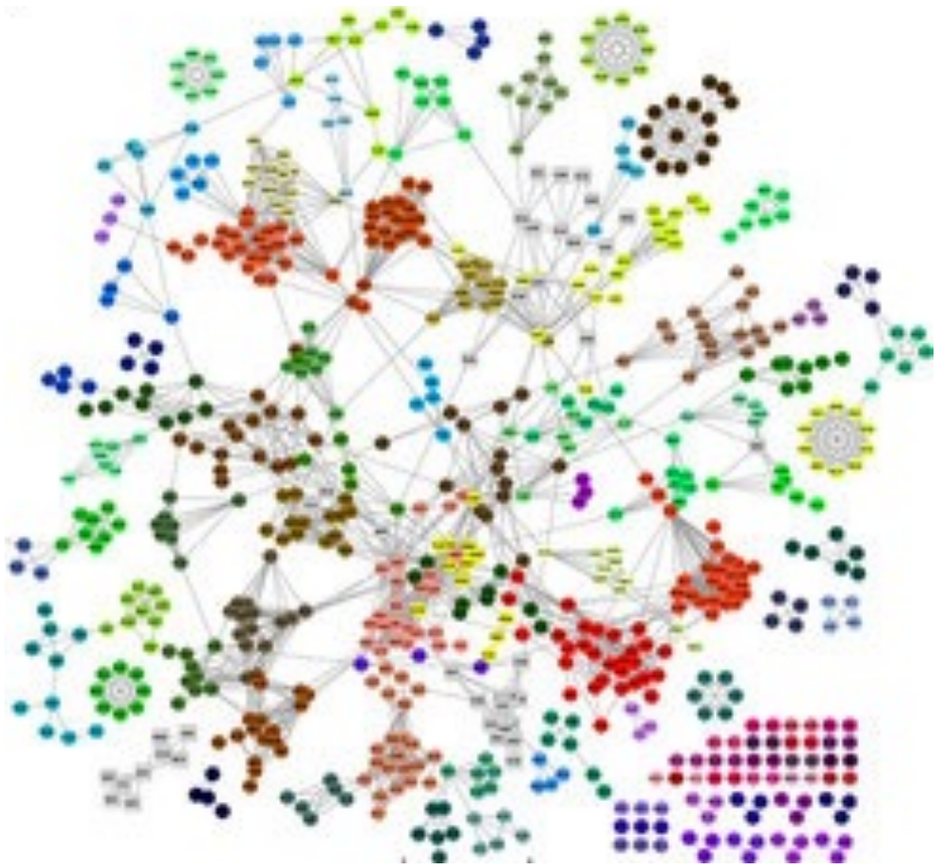
- Small-World Graph: Start with a *N* nodes, generate a regular graph connect each of them with *k/2* neighbors on each side. Rewire each of them with a probability *P*.

- Scale-Free Graph: Network of *N* nodes and *kN* edges. Start with k+1 nodes. Add one node at the time connecting *k* edges to the previous nodes with probability proportional to the number of edges of each of them (see example with *k=2*).



Community or Cluster

One of the main feature of the biological network is the presence of subset of nodes densely interconnected (communities or clusters)



Gaiter, Scientific Reports 2015

Clusters are important to detect similarity between nodes (genes, diseases, etc) in the same cluster.

Network Robustness

Robustness, the ability to withstand failures and perturbations. It is a critical attribute of many complex systems including biological networks.

Robustness is tested removing nodes and checking if connections between the remaining nodes are conserved. This is possible because may exist alternative paths between two distinct nodes.

Biological networks persists despite the environmental noise, mutations etc.

Telecommunication networks resit to the attach of hackers and hardware failure

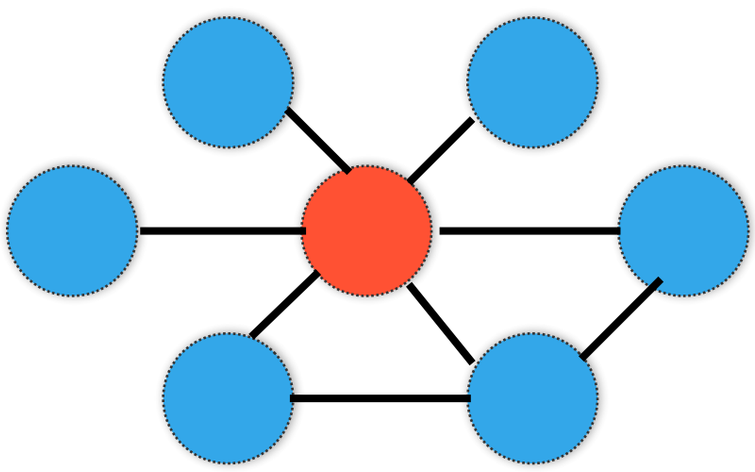
Network Perturbation

For random networks the effect of removing a single node is on average the same.

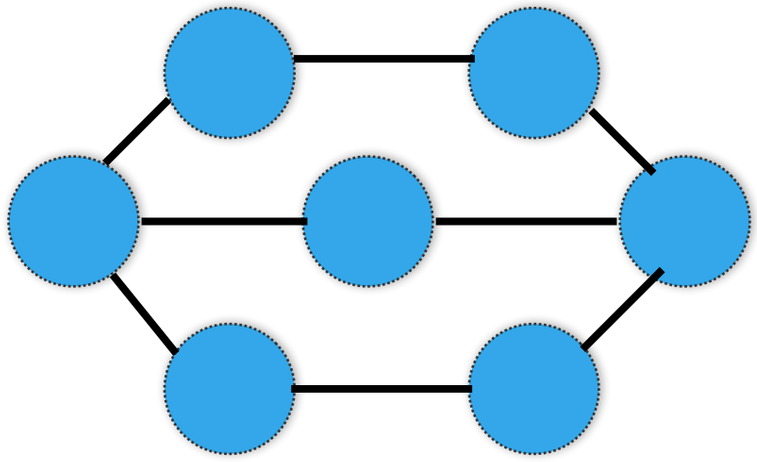
Biological networks are characterized by a small fraction of nodes with high degree (hubs)

An attack that aims to a hub has strong effect on the connectivity of the network.

In normal situation we assume that attacks are random. Thus, on average, an attach should have smaller effect on Biological Network.



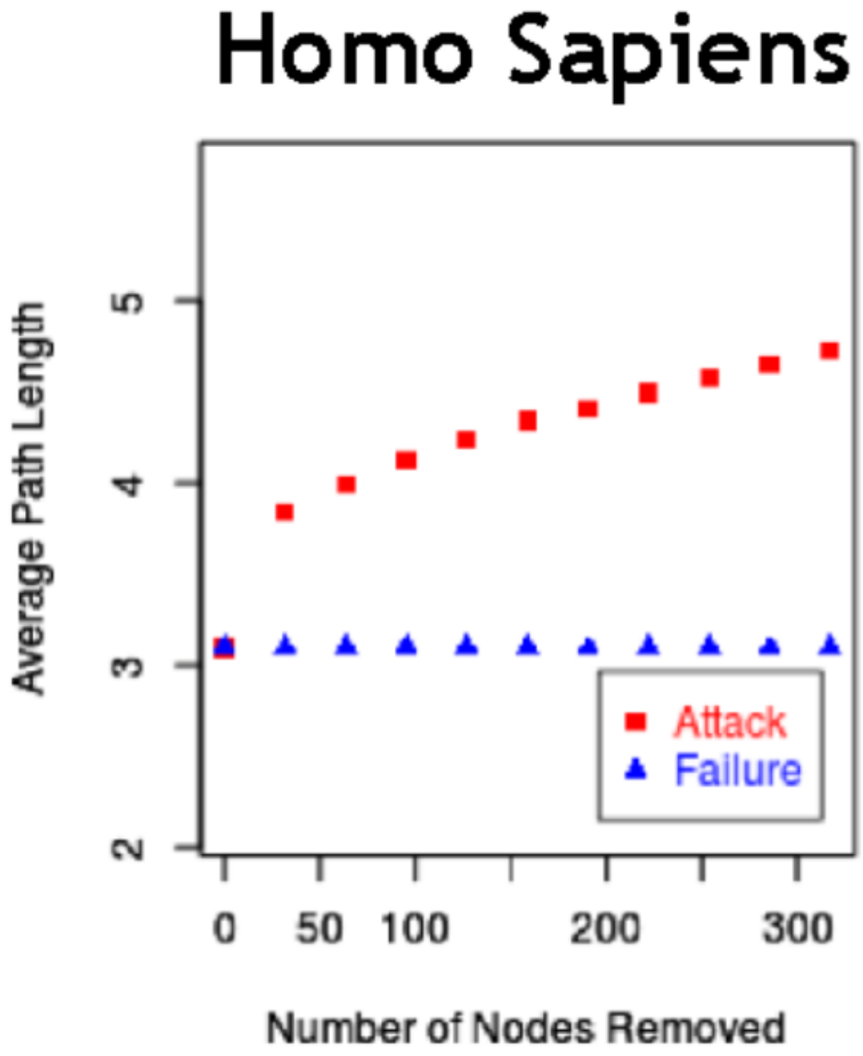
Biological network

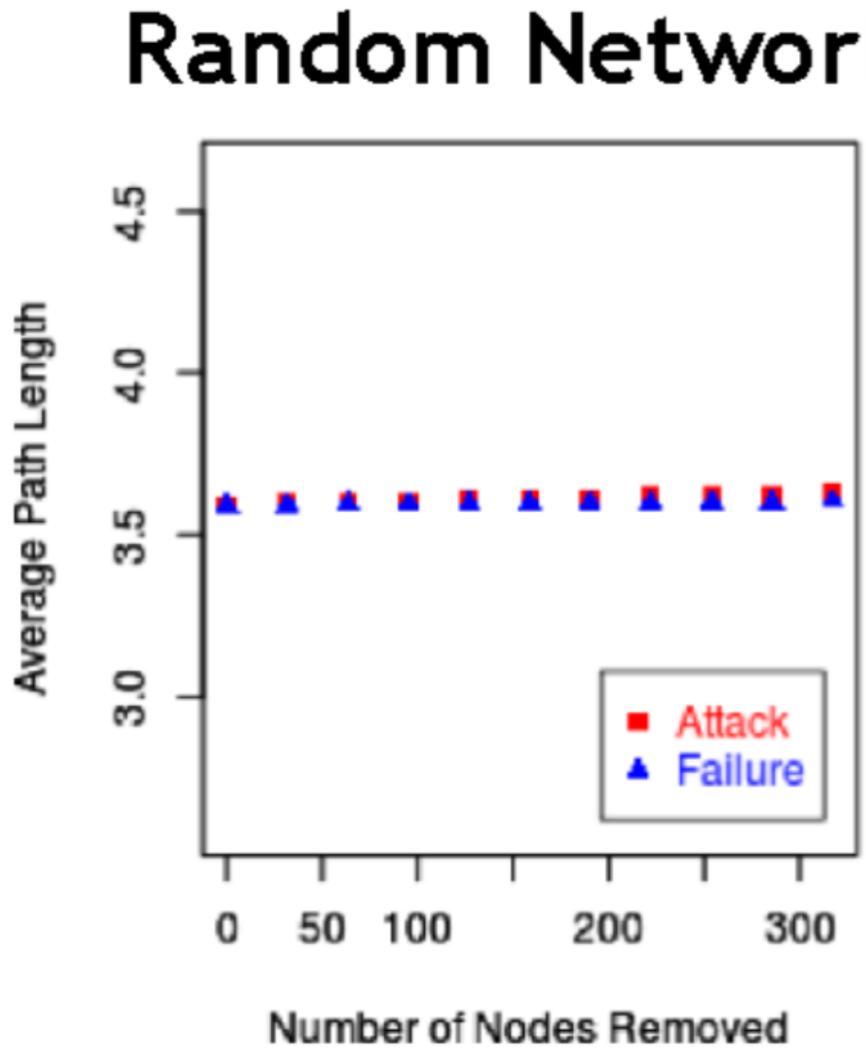


Random network

Failures and Attacks

The resilience of scale free networks to failures comes at the price of high vulnerability to targeted attacks





Python NetworkX

NetworkX is a Python package for the creation, manipulation, and study of the structure, dynamics, and functions of complex networks.

```
>>> import networkx as nx
>>> G = nx.Graph()

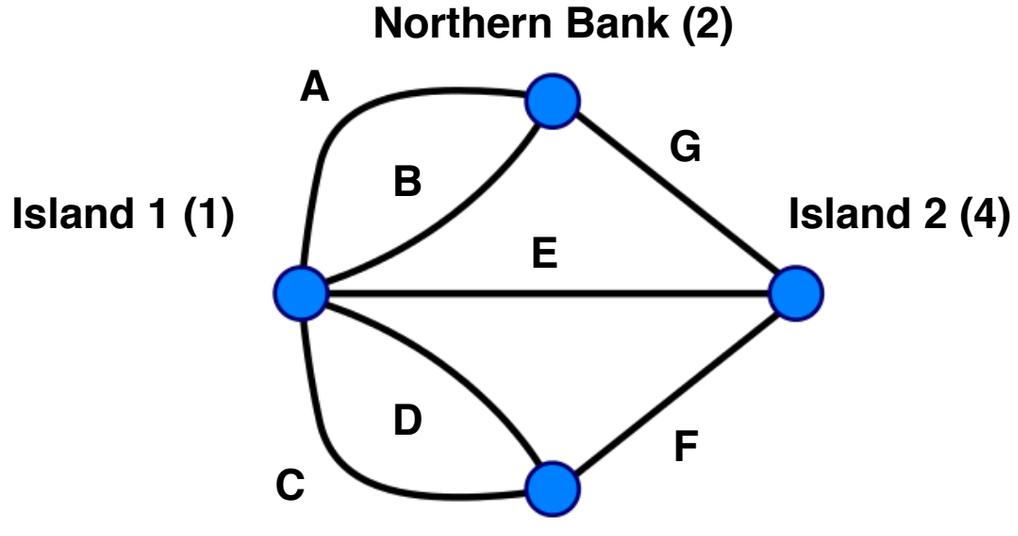
>>> G.add_node(1)
>>> G.add_nodes_from([2, 3]) # add list of nodes

>>> G.add_edge(1, 2)
>>> G.add_edges_from([(1, 2), (1, 3)]) # add list of edges

>>> G.number_of_nodes()
3
>>> G.number_of_edges()
2
```

Könisberg Graph

NetworkX allows to create graphs with
multiple edges connecting the same nodes
using the MultiGraph object.



```
>>> import networkx as nx
>>> M = nx.MultiGraph()

>>> M.add_edges_from([(1, 2, {“name”:“A”}),
...                   (1, 2, {“name”:“B”}), (1, 3, {“name”:“C”}),
...                   (1, 3, {“name”:“D”}), (1, 4, {“name”:“E”}),
...                   (3, 4, {“name”:“F”}), (2, 4, {“name”:“G”})])

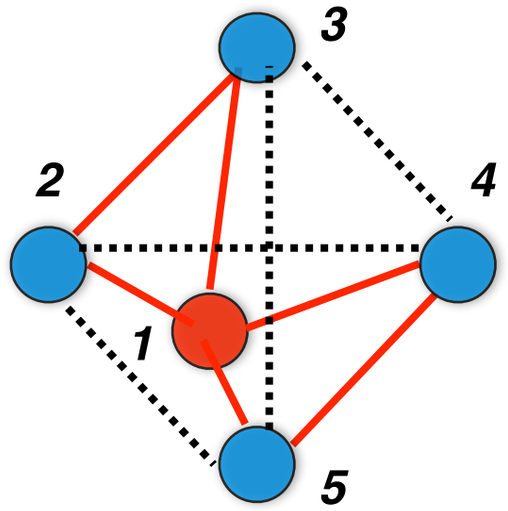
>>> M = M.degree(1)
```

Exercise

- Calculate the clustering coefficient of node 1

  c(1) = the number of triangles with fix vertex in node 1 divided by the all possible triangles.

  triangles = [(1,2,3),(1,4,5)]
  other triangles = [(1,3,4), (1,2,5), (1,2,4), (1,3,5)]

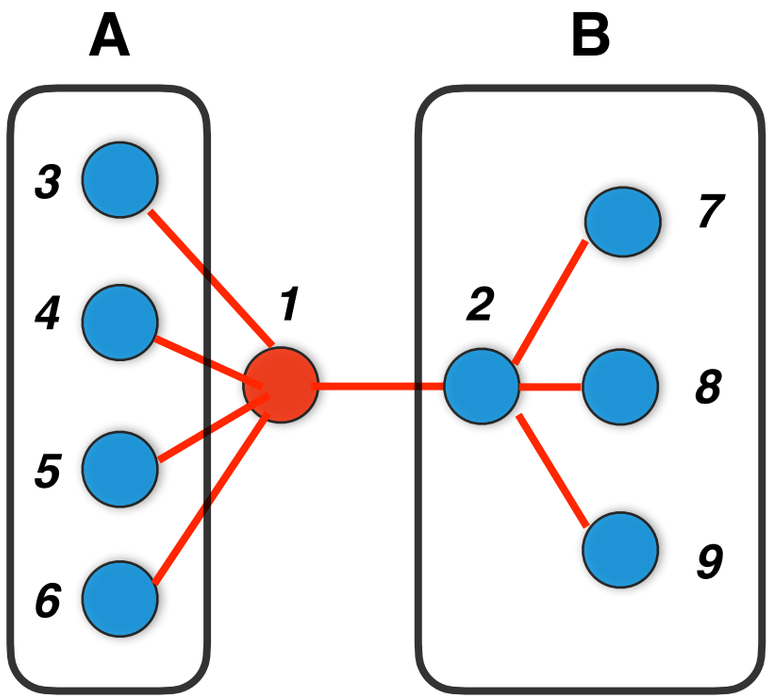


- Calculate the number of shortest paths passing through node 1

  $\sigma(1)$ = all the paths from block A to block B
  + all the possible paths between nodes within block A

  3 → 2, 7, 8, 9
  4 → 2, 7, 8, 9
  5 → 2, 7, 8, 9
  6 → 2, 7, 8, 9

  3 → 4, 5, 6
  4 → 5, 6
  5 → 6



Network generators

Networkx has function that generate standard network types

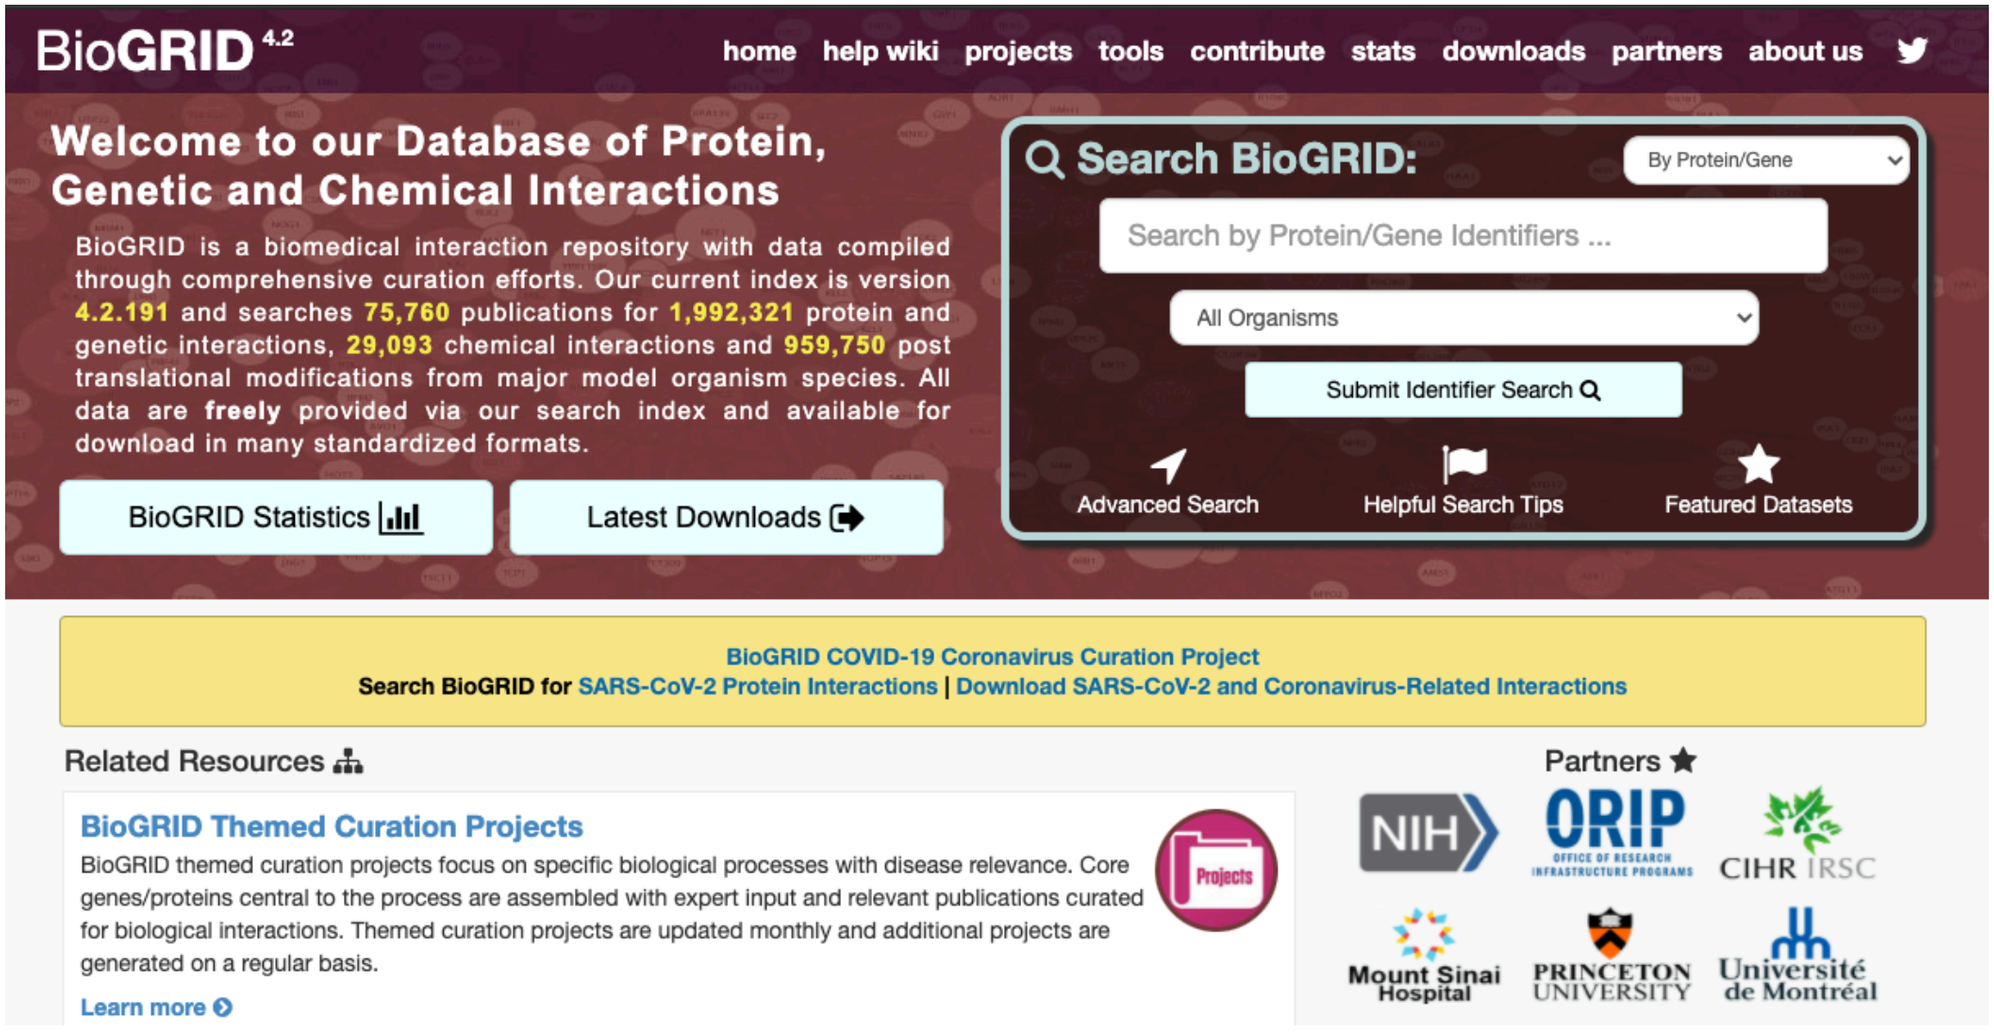
```
>>> import networkx as nx
>>> import matplotlib.pyplot as plt
```

```
>>> er = nx.erdos_renyi_graph(100, 0.15)
>>> ws = nx.watts_strogatz_graph(30, 3, 0.1)
>>> ba = nx.barabasi_albert_graph(100, 5)

>>> nx.draw(ba)
>>> plt.show()
```

BioGRID

The Biological General Repository for Interaction Datasets (BioGRID) is a curated biological database of protein-protein interactions, genetic interactions, chemical interactions, and post-translational modifications



https://thebiogrid.org/

Exercise

Generate the three types of network (random,"small world" and "scale free") and calculate the distribution of the degree, betweenness and clustering.

From BioGRID download the Yeast interactome and analyze it with networkx importing only a list of unique interactions from the BIOGRID repository:

- How many components are present?
- What is the gene with highest degree?
- What is the the average values of degrees, betweenness and clustering?
- Draw the distribution of the degree and fit to a power law distribution
